Abstract

- Food delivery applications have become an essential part of daily life.
- Existing order tracking systems often face delays, inaccurate delivery updates, and poor communication.
- This project focuses on improving real-time order tracking using GPS, AI-based route optimization, and instant customer notifications.
- The proposed system enhances delivery accuracy, reduces waiting time, and improves customer satisfaction.
- It also helps restaurants and delivery partners manage orders efficiently.

Introduction

- Online food delivery has grown rapidly due to convenience and digital technology.
- Customers expect accurate and real-time order tracking.
- Existing systems sometimes provide delayed or incorrect status updates.
- An improved tracking system increases trust between customers and service providers.
- This project aims to provide a smarter and more efficient food delivery tracking solution.

Problem Statement

- Inaccurate real-time location updates.
- Delay in notifying customers about order status.
- Traffic and route changes affect delivery time.
- Poor communication between customers and delivery agents.
- Lack of intelligent prediction for Estimated Time of Arrival (ETA).

Model 1 – Basic GPS Tracking System

- The system uses GPS technology to track the live location of the delivery partner.
- Customers can view the order status, such as Order Confirmed, Food Being Prepared, Picked Up, and Delivered.
- Basic notifications are sent whenever the order status changes.
- The estimated delivery time is calculated based on the distance between the delivery partner and the customer.
- This model is simple, cost-effective, and suitable for basic food delivery applications

Model 2 – Smart Route Optimization System

- This model combines GPS tracking with real-time traffic analysis to find the fastest delivery route.
- It continuously updates the Estimated Time of Arrival (ETA) based on traffic conditions.
- Customers receive instant notifications if there is any delivery delay.
- Delivery partners are guided through the most efficient route, reducing travel time and fuel consumption.
- This model improves delivery speed, accuracy, and overall customer satisfaction.

Model 3 – AI-Based Intelligent Order Tracking System

- This advanced model uses Artificial Intelligence (AI) and Machine Learning to predict delivery time more accurately.
- The system analyzes traffic, weather, historical delivery data, and road conditions to recommend the best route.
- It automatically detects possible delays and sends proactive alerts to customers before they occur.
- AI helps restaurants and delivery partners manage orders more efficiently by optimizing delivery schedules.
- This model provides faster deliveries, better resource management, and a highly reliable tracking experience for customers.

Limitations

- Depends on a stable internet connection for real-time tracking.
- GPS location accuracy may be affected in crowded or indoor areas.
- Traffic conditions and weather can still cause unexpected delivery delays.
- AI predictions may not always be 100% accurate due to changing conditions.

Future Scope

- Integration with drones for food delivery.
- AI-based personalized delivery recommendations.
- Voice assistant support for order tracking.
- Blockchain technology for secure order management.
- IoT-enabled smart delivery monitoring.

Conclusion

- The proposed system improves the accuracy of order tracking.
- Real-time updates increase customer satisfaction.
- AI and GPS technologies reduce delivery delays.
- Smart route optimization improves delivery efficiency.
- The system benefits customers, restaurants, and delivery partners.
